Hysterectomy is the most frequently performed Gynecological procedure worldwide. Although the Abdominal or the Vaginal approach have been the norm, recently there has been an increased interest and acceptance of the Laparoscopic approach. Various recommendations have been suggested and it is now generally accepted that most Hysterectomies for benign uterine disease should be performed vaginally or Laparoscopically instead of the abdominal approach and every effort should be made to facilitate this attitude in the best interest of the patients. Despite the advent of safer techniques and abundant advantages of Laparoscopic Hysterectomies, the abdominal approach still remains the preferred approach and the uptake and adoption of this remarkable procedure seems to be rather slow. Inadequate, insufficient exposure, experience and training, lack of sufficient Hospital equipment and lack of support from colleagues have been some of the limiting factors. There has been a significant shift of performing Total Laparoscopic Hysterectomies as Day care procedures world over with remarkable success. A review of Total Laparoscopic Hysterectomies performed by the author is presented.
